

SIMULATION OF LASER-COMPTON COOLING OF ELECTRON BEAMS*

TOMOMI OHGAKI

*Lawrence Berkeley National Laboratory
Berkeley, California 94720, USA*

We study a method of laser-Compton cooling of electron beams. Using a Monte Carlo code, we evaluate the effects of the laser-electron interaction for transverse cooling. The optics with and without chromatic correction for the cooling are examined. The laser-Compton cooling for JLC/NLC at $E_0 = 2$ GeV is considered.

1. Introduction

A novel method of electron beam cooling for future linear colliders was proposed by V.Telnov.¹ During head-on collisions with laser photons, the transverse distribution of electron beams remains almost unchanged and also the angular spread is almost constant. Because the Compton scattered photons follow the initial electron trajectory with a small additional spread due to much lower energy of photons (a few eV) than the energy of electrons (several GeV). The emittance $\epsilon_i = \sigma_i \sigma'_i$ remains almost unchanged ($i = x, y$). At the same time, the electron energy decreases from E_0 to E_f . Thus the normalized emittances have decreased as follows

$$\epsilon_n = \gamma \epsilon = \epsilon_{n0} (E_f / E_0) = \epsilon_{n0} / C, \quad (1)$$

where ϵ_{n0} , ϵ_n are the initial and final normalized emittances, the factor of the emittance reduction $C = E_0 / E_f$. The method of electron beam cooling allows further reduction of the transverse emittances after damping rings or guns by 1-3 orders of magnitude.¹

In this paper, we have evaluated the effects of the laser-Compton interaction for transverse cooling using the Monte Carlo code CAIN.² The simulation calculates the effects of the nonlinear Compton scattering between the laser photons and the electrons during a multi-cooling stage. Next, we examine the optics for cooling with and without chromatic correction. The laser-Compton cooling for JLC/NLC³ at $E_0 = 2$ GeV is considered in section 4. A summary of conclusion is given in section 5.

Table 1. Parameters of the electron beams for laser-Compton cooling. The value in the parentheses is given by Telnov's formulas.

E_0 (GeV)	E_f (GeV)	C	$\epsilon_{n,x}/\epsilon_{n,y}$ (m-rad)	β_x/β_y (mm)	σ_z (mm)	δ (%)
2	0.2	10	$7.4 \times 10^{-8}/2.9 \times 10^{-8}$	4/4	0.5	11 (9.8)
5	1	5	$3.0 \times 10^{-6}/3.0 \times 10^{-6}$	0.1/0.1	0.2	19 (19)

Table 2. Parameters of the laser beams for laser-Compton cooling. The value in the parentheses is given by Telnov's formulas.

E_0 (GeV)	λ_L (μm)	x_0	A (J)	ξ	$R_{L,x}/R_{L,y}$ (mm)	$\sigma_{L,z}$ (mm)
2	0.5	0.076	300 (56)	2.1 (2.2)	0.3/0.3	1.25
5	0.5	0.19	20 (4)	1.5 (1.5)	0.1/0.1	0.4

2. Laser-Electron Interaction

2.1. Laser-Electron Interaction

In this section, we describe the main parameters for laser-Compton cooling of electron beams. A laser photon of energy ω_L (wavelength λ_L) is backward-Compton scattered by an electron beam of energy E_0 in the interaction point (IP). The kinematics of Compton scattering is characterized by the dimensionless parameter¹

$$x_0 \equiv \frac{4E_0\omega_L}{m_e^2c^4} = 0.019 \frac{E_0[\text{GeV}]}{\lambda_L[\mu\text{m}]}, \quad (2)$$

where m_e is electron mass. The parameters of the electron and laser beams for laser-Compton cooling are listed in Tables 1 and 2. The parameters of the electron beam with 2 GeV are given for JLC/NLC case in section 4. The parameters of that with 5 GeV are used for simulation in the next subsection. The wavelength of laser is assumed to be 0.5 μm . The parameters of x_0 with the electron energies 2 GeV and 5 GeV are 0.076 and 0.19, respectively.

The required laser flush energy with $Z_R \ll l_\gamma \simeq l_e$ is¹

$$A = 25 \frac{l_e[\text{mm}]\lambda_L[\mu\text{m}]}{E_0[\text{GeV}]}(C-1) [\text{J}], \quad (3)$$

where Z_R , l_γ ($\sim 2\sigma_{L,z}$), and l_e ($\sim 2\sigma_z$) are the Rayleigh length of laser, and the bunch lengths of laser and electron beams. From this formula, the parameters of A with the electron energies 2 GeV and 5 GeV are 56 J and 4 J, respectively.

The nonlinear parameter of laser field is¹

$$\xi^2 = 4.3 \frac{\lambda_L^2[\mu\text{m}^2]}{l_e[\text{mm}]E_0[\text{GeV}]}(C-1). \quad (4)$$

In this study, for the electron energies 2 GeV and 5 GeV, the parameters of ξ are 2.2 and 1.5, respectively.

The rms energy of the electron beam after Compton scattering is¹

$$\sigma_e = \frac{1}{C^2} [\sigma_{e0}^2[\text{GeV}^2] + 0.7x_0(1 + 0.45\xi)(C-1)E_0^2[\text{GeV}^2]]^{1/2} [\text{GeV}], \quad (5)$$

where the rms energy of the initial beam is σ_{e0} and the ratio of energy spread is defined as $\delta = \sigma_e/E_f$. If the parameter ξ or x_0 is larger, the energy spread after Compton scattering is increasing and it is the origin of the emittance growth in the defocusing optics, reacceleration linac, and focusing optics. The energy spreads δ for the electron energies 2 GeV and 5 GeV are 9.8% and 19%, respectively.

The equilibrium emittances due to Compton scattering are¹

$$\epsilon_{ni,\min} = \frac{7.2 \times 10^{-10} \beta_i [\text{mm}]}{\lambda_L [\mu\text{m}]} \quad (i = x, y) \quad [\text{m} \cdot \text{rad}], \quad (6)$$

where β_i are the beta functions at IP. From this formula we can see that small beta gives small emittance. However the large change of the beta functions between the magnet and the IP causes the emittance growth. Taking no account of the emittance growth, for the electron energies 2 GeV and 5 GeV, the equilibrium emittances are 5.8×10^{-9} m·rad and 1.4×10^{-10} m·rad, respectively. The equilibrium emittances depended on ξ in the case $\xi^2 \gg 1$ were calculated in Ref. 1.

2.2. Simulation of Laser-Electron Interaction

For the simulation of laser-electron interaction, the electron beam is simply assumed to be a round beam in the case of $E_0 = 5$ GeV and $C = 5$. Taking no account of the emittance growth of optics, the one stage for cooling consists two parts as follows:

1. The laser-Compton interaction between the electron and laser beams.
2. The reacceleration of electrons in linac.

In the first part, we simulated the interactions by the CAIN code.² This simulation calculates the effects of the nonlinear Compton scattering between the laser photons and the electrons. We assume that the laser pulse interacts with the electron bunch in head-on collisions. The β_x and β_y at the IP are fixed to be 0.1 mm. The initial energy spread of the electron beams is 1%. The energy of laser pulse is 20 J. The difference of the pulse energy between the simulation and the formula depends on the transverse sizes of the electron beams at IP. The polarization of the electron and laser beams are $P_e=1.0$ and $P_L=1.0$ (circular polarization), respectively. When the x_0 and ξ parameters are small, the spectrum of the scattered photons does not largely depend on the polarization combination. In order to accelerate the electron beams to 5 GeV for recovery of energy in the second part, we simply added the energy $\Delta E = 5 \text{ GeV} - E_{ave}$ for reacceleration, where E_{ave} is the average energy of the scattered electron beams after the laser-Compton interaction.

Here we define the transverse, longitudinal, and 6D emittances in the simulation. The x, y -transverse emittance is

$$\epsilon_{n,i} = \sqrt{\sigma_i^2 \sigma_{i'}^2 - (\langle i \cdot i' \rangle - \langle i \rangle \langle i' \rangle)^2} \quad (i = x, y), \quad (7)$$

where the symbol $\langle \rangle$ means to take an average of all particles in a bunch.

The longitudinal emittance is

$$\epsilon_{n,l} = \sqrt{\sigma_z^2 \sigma_{p_z}^2 - (\langle z \cdot p_z \rangle - \langle z \rangle \langle p_z \rangle)^2} / (m_e c). \quad (8)$$

The 6D emittance is defined as

$$\epsilon_{6N} = \epsilon_{n,x} \cdot \epsilon_{n,y} \cdot \epsilon_{n,l}. \quad (9)$$

Figure 1 shows the longitudinal distribution of the electrons after the first laser-Compton scattering. The average energy of the electron beams is 1.0 GeV and the energy spread δ is 0.19. The longitudinal distribution seems to be a boomerang. If we assume a short Rayleigh length of laser pulse, the energy loss of head and tail of beams is small. The number of the scattered photons per incoming particle and the average of the photon energy at the first stage are 40 and 96 MeV (rms energy 140 MeV), respectively.

Fig. 1. The longitudinal distribution of the electrons. (a) The energy *vs.* *z*. (b) The energy distribution of the electrons. The bin size is 40 MeV.

Fig. 2. The transverse sizes of the electron beams.

Fig. 3. The angles of the electron beams.

The transverse sizes of the electron beams in the multi-stage cooling are shown in Fig. 2. During collisions with the laser photons, the transverse distribution of the electrons remains almost unchanged. But they decrease when we focus them for the next laser-Compton interaction due to the lower normalized emittance and the fixed β -function at IP ($\sigma_i = \sqrt{\beta_i \epsilon_{n,i} / \gamma}$). The angles of the electron beams in the multi-stage cooling are shown in Fig. 3. As a result of reacceleration, the angles of the electrons decrease. They increase when we focus them for the next laser-Compton interaction. Finally the angles attain the average of Compton scattering angle and the effect of cooling saturates.

Figure 4 shows the transverse emittances of the electron beams in the multi-stage cooling. From Eq.(6), $\epsilon_{ni,\min} = 1.4 \times 10^{-10}$ m-rad, and the simulation presents $\epsilon_{ni,\min} = 1.2 \times 10^{-9}$ m-rad. Figure 5 shows the longitudinal emittance of the electron beams in the multi-stage cooling. Due to the increase of the energy spread of the electron beams from 1% to 19%, the longitudinal emittance rapidly increases at the first stage. After the first stage, the normalized longitudinal emittance is stable. The 6D emittance of the electron beams in the multi-stage cooling is shown in Fig. 6. The second cooling stage has the largest reduction for cooling. The 8th or 9th cooling stages have small reduction for cooling. The initial and final 6D emittances ϵ_{6N} are 1.5×10^{-13} (m-rad)³ and 1.2×10^{-19} (m-rad)³, respectively.

Figure 7 shows the polarization of the electron beams in the multi-stage cooling. The decrease of the polarization during the first stage is about 0.06. The final polarization P_e after the multi-stage cooling is 0.54.

Fig. 4. The transverse emittances of the electron beams.

Fig. 5. The longitudinal emittance of the electron beams.

3. Optics Design for Laser-Compton Cooling

3.1. Optics without chromaticity correction

There are three optical devices for the laser-Compton cooling of electron beams as follows:

1. The focus optics to the first IP.

Fig. 6. The 6D emittance of the electron beams. Fig. 7. The polarization of the electron beams.

2. The defocus optics from the first IP to the reacceleration linac.
3. The focus optics from the linac to the next IP.

Figure 8 shows schematics of the laser-Compton cooling of electron beams. The optics 1 is focusing the electron beams from a few meters of β -function to several millimeters in order to effectively interact them with the laser beams. The optics 2 is defocusing them from several millimeters to a few meters for reacceleration of electron beams in linac. In a multi-stage cooling system, the optics 3 is needed for cooling in the next stage. The problem for the focus and defocus optical devices is the energy spread of electrons and the electron beams with a large energy spread are necessary to minimize or correct the chromatic aberrations avoiding emittance growth.

Fig. 8. Schematics of the laser-Compton cooling of electron beams.

In this subsection, we discuss the optics for laser-Compton cooling without chromatic corrections. For the focus and defocus of the beams, we use the final doublet system which is similar to that of the final focus system of the future linear colliders.³ The pole-tip field of the final quadrupole B_T is limited to 1.2 T and the pole-tip radius a is greater than 3 mm. The strength of the final quadrupole is

$$\kappa = B_T / (aB\rho) \leq 120/E[\text{GeV}] [\text{m}^{-2}], \quad (10)$$

where B , ρ , and E are the magnetic field, the radius of curvature and the energy of the electron beams. In our case, the electron energies in the optics 1, 2, and 3 are 5.0, 1.0, and 5.0 GeV, respectively and the limit of the strength of the quadrupole

in laser cooling is much larger than that of the final quadrupole of the future linear colliders. Due to the low energy beams in laser cooling, the synchrotron radiation from quadrupoles and bends is negligible.

The difference of three optical devices is the amount of the energy spread of the beams. In the optics 1, 2, and 3, the beams have one, several tens, and a few % energy spread. In order to minimize the chromatic aberrations, we need to shorten the length between the final quadrupole and the IP. In this study, the length from the face of the final quadrupole to the IP, l is assumed to be 2 cm. Here we estimated the emittance growth in the optics 2, because the chromatic effect in the optics 2 is the most serious. Figure 9 shows the defocus optics without chromaticity correction for laser-Compton cooling by the MAD code.⁴ The input file is attached to Ref. 5. The parameters of the electron beam for laser-Compton cooling at $E_0 = 5$ GeV and $C = 5$ are listed in Table 3. The initial β_x and β_y after laser-Compton interaction are 20 mm and 4 mm, respectively. The final β_x and β_y are assumed to be 2 m and 1 m, respectively. The initial and final $\alpha_{x(y)}$ with no energy spread $\delta = 0$ are 0 in this optics. The strength κ of the final quadrupole for the beam energy of 1 GeV from Eq. (10) is assumed to be 120 m⁻².

Table 3. Parameters of the electron beam for laser-Compton cooling at $E_0 = 5$ GeV and $C = 5$ for the optics design.

E_0 (GeV)	$\epsilon_{n,x}/\epsilon_{n,y}$ (m·rad)	β_x/β_y (mm)	σ_x/σ_y (m)	σ_z (mm)
5	$1.06 \times 10^{-6}/1.6 \times 10^{-8}$	20/4	$3.3 \times 10^{-5}/1.8 \times 10^{-7}$	0.2

In our case, the chromatic functions ξ_x and ξ_y are 18 and 148, respectively. The momentum dependence of the emittances in the defocus optics without chromaticity correction is shown in Fig. 10. In the paper,⁶ the analytical study by thin-lens approximation has been studied for the focusing system, and here the transverse emittances are calculated by a particle-tracking simulation. The 10000 particles are tracked for the transverse and longitudinal Gaussian distribution by the MAD code. The relative energy spread δ is changed from 0 to 0.4. Due to the larger chromaticity ξ_y , the emittance ϵ_y is rapidly increasing with the energy spread δ . If we set a limit of 200% for $\Delta\epsilon_i/\epsilon_i$ ($i = x, y$), the permissible energy spread δ_x and δ_y are 0.11 and 0.012 which mean the momentum band widths $\pm 22\%$ and $\pm 2.4\%$, respectively. The results are not sufficient for cooling at $E_0 = 5$ GeV and $C = 5$, because the beams through the defocusing optics have the energy spread of several tens %. On the one hand, the optics can be useful as the optics 1 and 3 with the energy spread of a few %.

3.2. Optics with chromaticity correction

The optics without chromaticity correction for the optics 2 does not work as we saw in the previous subsection. In this subsection we apply the chromaticity correction for the optics 2. The lattice for cooling is designed referring to the final focus system of the future linear colliders by K. Oide.⁷ The final doublet system

Fig. 9. The defocus optics without chromaticity correction for laser-Compton cooling.

Fig. 10. Momentum dependence of the emittances in the defocus optics without chromaticity correction.

is the same lattice as the optics before subsection. The method of chromaticity correction uses one family of sextupole to correct for vertical chromaticity and moreover we added two weak sextupoles in the lattice to correct for horizontal chromaticity. Figure 11 shows the defocus optics with chromaticity correction for the laser-Compton cooling. The input file is attached to Ref. 5. The total length of the lattice is about 63 m.

The momentum dependence of the emittances in the defocus optics with chromaticity correction is shown in Fig. 12. The 10000 particles are tracked for the transverse and longitudinal Gaussian distribution by the MAD code. The relative energy spread δ is changed from 0 to 0.06 with the conservation $\kappa_2 \theta_B$, where κ_2 and θ_B are the strength of the sextupole and the angle of the bending magnet. The initial β_x and β_y after laser-Compton interaction are 20 mm and 4 mm, respectively. The final β_x and β_y are assumed to be 2 m and 1 m, respectively. The initial and final $\alpha_x(y)$ with no energy spread $\delta = 0$ are 0 in this optics. After the chromaticity correction, the chromaticity functions ξ_x and ξ_y are 9.3 and 1.6, respectively. If we set a limit of 200% for $\Delta\epsilon_i/\epsilon_i (i = x, y)$, the permissible energy spread δ_x and δ_y are 0.040 and 0.023 which mean the momentum band widths $\pm 8\%$ and $\pm 4.6\%$, respectively. By the comparison with the results of the optics without chromaticity correction at a limit of 200% for $\Delta\epsilon_i/\epsilon_i (i = x, y)$, the ϵ_y of the optics with chromaticity correction is about two times larger than that of the one before subsection,

but the ϵ_x of the optics with chromaticity correction is three times smaller than that of the one before. The results are still not sufficient for cooling with $E_0 = 5$ GeV and $C = 5$. These results emphasize the need to pursue further ideas for plasma lens.⁸

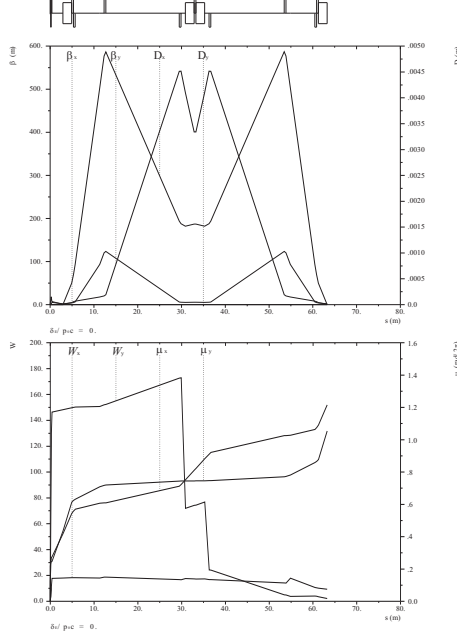

Fig. 11. The defocus optics without chromaticity correction for laser-Compton cooling.

Fig. 12. Momentum dependence of the emittances in the defocus optics with chromaticity correction.

4. Laser-Compton Cooling for JLC/NLC at $E_0 = 2$ GeV

4.1. Optics

For the future linear colliders, the method of laser-Compton cooling is effective to reduce the transverse emittances after damping rings. Where can it be placed? There are two possibilities for JLC/NLC⁹ as follows:

1. After the first bunch compressor (BC1) and before the pre-linac. $E_0 = 2$ GeV and $\sigma_z = 0.5$ mm.
2. After the second bunch compressor (BC2) and before the main linac. $E_0 = 10$ GeV and $\sigma_z = 0.1$ mm.

Case 2 needs a large energy for recovery after Compton scattering and we consider case 1 in this study. The parameters of the electron and laser beams for laser-Compton cooling for JLC/NLC at $E_0 = 2$ GeV and $C = 10$ are listed in Tables 1 and 2. The energy of laser pulse is 300 J. The simulation results of the laser-electron

interaction by the CAIN code are summarized as follows. The energy spread of the electron beam is 11%. The decrease of the longitudinal polarization of the electron beam is 0.038 ($P_e = 1.0, P_L = 1.0$). The number of the scattered photons per incoming particle and the average of the photon energy are 200 and 8.9 MeV (rms energy 19 MeV), respectively.

Table 4. Parameters of the defocus optics for laser-Compton cooling for JLC/NLC at $E_0=2$ GeV and $C = 10$.

l	Length of Q1	Field of Q1	Aperture	Total length
5 mm	2 cm	1.2 Tesla	0.5 mm	7.4 cm

The electron energy after Compton scattering in case 2 is 0.2 GeV and the strength of the final quadrupole from Eq. (10) is 600 m^{-2} . Table 4 lists the parameters of the defocusing optics for laser-Compton cooling for JLC/NLC at $E_0 = 2$ GeV and $C = 10$. The final β_x and β_y are assumed to be 1 m and 0.25 m, respectively. The chromaticity functions ξ_x and ξ_y are 18 and 23, respectively. Using the MAD code, the emittance growth in the defocus optics are

$$\Delta\epsilon_{n,x}^{\text{defocus}} = \epsilon_{n,x} - \epsilon_{n,x0} \sim 1.0\epsilon_{n,x0} \sim 7.6 \times 10^{-8} [\text{m} \cdot \text{rad}], \quad (11)$$

$$\Delta\epsilon_{n,y}^{\text{defocus}} = \epsilon_{n,y} - \epsilon_{n,y0} \sim 1.6\epsilon_{n,y0} \sim 4.6 \times 10^{-8} [\text{m} \cdot \text{rad}], \quad (12)$$

where the normalized emittances before and after the defocus optics are $\epsilon_{n,i0}$ and $\epsilon_{n,i}$ ($i = x, y$), respectively. The emittance growth in the other two focus optics are negligible.

4.2. *Reacceleration Linac*

In the reacceleration linac, there are two major sources of the emittance increase⁹ as follows:

1. The emittance growth due to the misalignment of the quadrupole magnet and the energy spread.
2. The emittance growth due to the cavity misalignment.

The emittance growth due to these sources in the reacceleration linac (L-band linac) are formulated by K. Yokoya⁹

$$\Delta\epsilon_{n,x}^{\text{linac}} \sim 3.4 \times 10^{-9} [\text{m} \cdot \text{rad}] \sim 0.045\epsilon_{n,x0}, \quad (13)$$

$$\Delta\epsilon_{n,y}^{\text{linac}} \sim 3.4 \times 10^{-9} [\text{m} \cdot \text{rad}] \sim 0.12\epsilon_{n,y0}. \quad (14)$$

The final emittance growth and the final emittance with $C = 10$ are

$$\Delta\epsilon_{n,x} \sim 7.9 \times 10^{-8} [\text{m} \cdot \text{rad}] \sim 1.1\epsilon_{n,x0} \Rightarrow \epsilon_{n,x} \sim 0.21\epsilon_{n,x0}, \quad (15)$$

$$\Delta\epsilon_{n,y} \sim 4.9 \times 10^{-8} [\text{m} \cdot \text{rad}] \sim 1.7\epsilon_{n,y0} \Rightarrow \epsilon_{n,y} \sim 0.27\epsilon_{n,y0}. \quad (16)$$

The total reduction factor of the 4D transverse emittance of the laser-Compton cooling for JLC/NLC at $E_0 = 2$ GeV is about 18. The decrease of the polarization of the electron beam is 0.038 due to the laser-Compton interaction.

5. Summary

We have studied the method of laser-Compton cooling of electron beams. The effects of the laser-Compton interaction for cooling have been evaluated by the Monte Carlo simulation. From the simulation in the multi-stage cooling, we presented that the low emittance beams with $\epsilon_{6N} = 1.2 \times 10^{-19}(\text{m}\cdot\text{rad})^3$ can be achieved in our beam parameters. We also examined the optics with and without chromatic correction for cooling, but the optics are not sufficient for cooling due to the large energy spread of the electron beams.

The laser-Compton cooling for JLC/NLC at $E_0 = 2$ GeV and $C = 10$ was considered. The total reduction factor of the 4D transverse emittance of the laser-Compton cooling is about 18. The decrease of the polarization of the electron beam is 0.038 due to the laser-Compton interaction.

Acknowledgments

We would like to thank Y. Nosochkov, K. Oide, T. Takahashi, V. Telnov, M. Xie, and K. Yokoya for useful comments and discussions.
